How To Develop and Build Angular App With Java Backend

Learn How you develop and build with an example project

Bhargav Bachina [Follow](#)

Apr 21, 2020 · 7 min read ★

Photo by [Martin Adams](#) on [Unsplash](#)

There are so many ways we can build Angular apps and ship for production. One way is

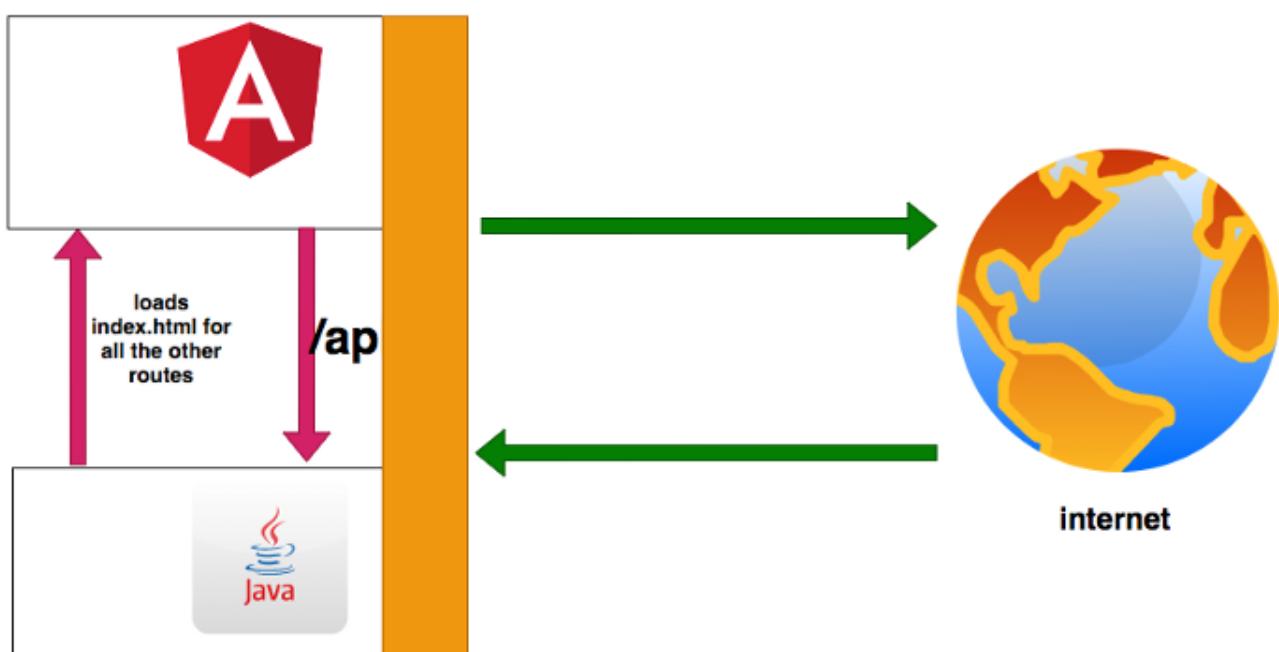

to build Angular with NodeJS or Java and another way is to build the angular and serve that static content with NGINX web server. With Java we have to deal with the server code as well, for example, you need to load index.html page with java.

In this post, we will see the details and implementation with Java. We will go through step by step with an example.

- *Introduction*
- *Prerequisites*
- *Example Project*
- *How To Build and Develop The Project*
- *How To Build For Production*
- *Summary*
- *Conclusion*

Introduction

Angular is a javascript framework for building web apps and it doesn't load itself in the browser. We need some kind of mechanism that loads the index.html (single page) of Angular with all the dependencies(CSS and js files) in the browser. In this case, we are using java as the webserver which loads Angular assets and accepts any API calls from the Angular app.

- Java

Angular with Java

- Angular CLI

If you look at the above diagram all the web requests without the `/api` will go to Angular

• TypeScript
routing. All the paths that contain `/api` will be handled by the Java server.

- VSCode
- ngx-bootstrap
- Maven

Example Project

This is a simple project which demonstrates developing and running Angular application with Java. We have a simple app in which we can add users, count, and display them at the side, and retrieve them whenever you want.

The screenshot shows a web browser window with the URL `localhost:4200` in the address bar. The page title is "Angular With Java". On the left, there is a "Create User" form with fields for First Name, Last Name, and Email, and a "Create" button. On the right, there is a green box titled "Users Created" containing the number "3" and a "Get All Users" button. Below the form is a table titled "Users" with columns: User Id, Firstname, Lastname, and Email. The table contains three rows of data.

User Id	Firstname	Lastname	Email
1	first	last 1	abc1@gmail.com
2	first	last 2	abc2@gmail.com
3	first	last 3	abc3@gmail.com

Example Project

As you add users we are making an API call to the Java server to store them and get the same data from the server when we retrieve them. You can see network calls in the following video.

The screenshot shows the same Angular application setup. On the right, the browser's developer tools Network tab is open, displaying a list of network requests. The table below shows the data from the "Users" table, and the Network tab shows the corresponding API calls made to the Java server.

User Id	Firstname	Lastname	Email
1	first	last 1	abc1@gmail.com
2	first	last 2	abc2@gmail.com
3	first	last 3	abc3@gmail.com
4	fsfsfs	sdfsdfsdf	sdfsdfsdfsdf
5	sdfsdf	sdfsdf	sdfsdfsdfsdf

Network Calls

Here is a Github link to this project. You can clone it and run it on your machine.

```
// clone the project  
git clone https://github.com/bbachi/angular-java-example.git
```

```
// Run Angular on port 4200
```

```
cd /src/main/ui  
npm install  
npm start
```

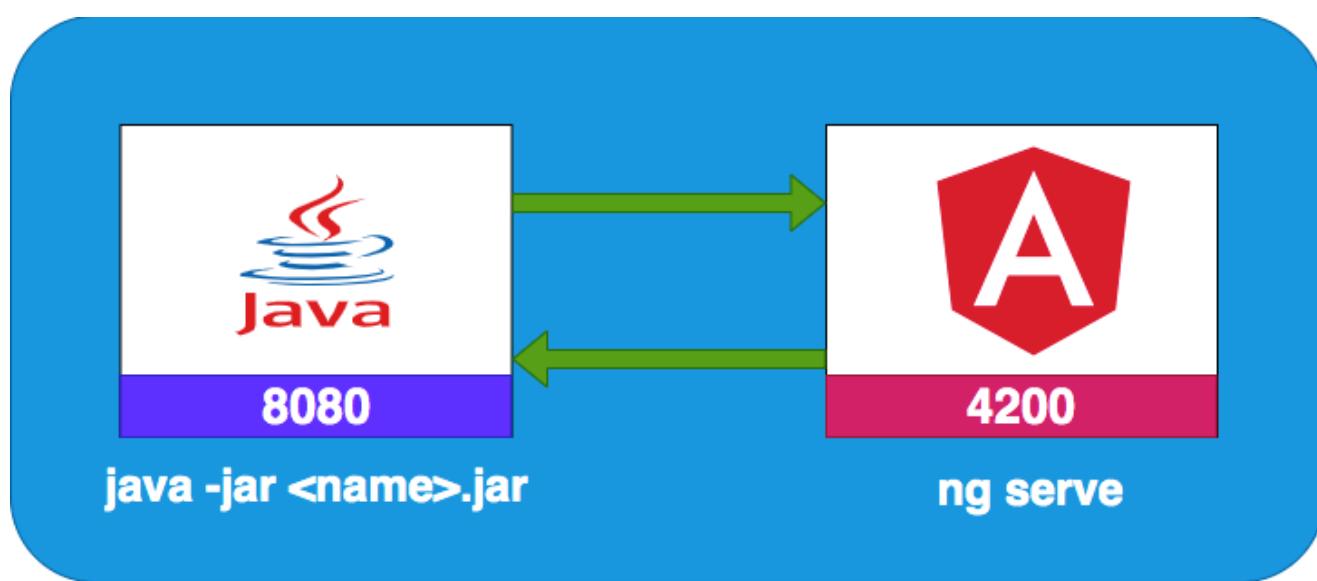

```
// Run Java Code on 8080
```

How To Build and Develop The Project

```
mvn clean install  
java -jar target/users-0.0.1-SNAPSHOT.jar
```

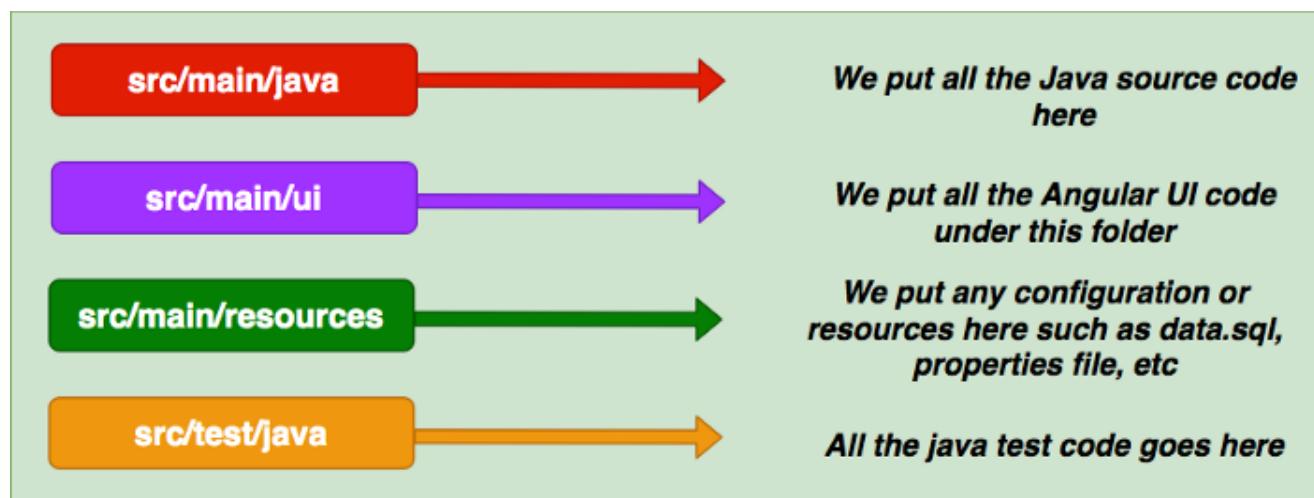

Usually, the way you develop and the way you build and run in production are completely different. That's why, I would like to define two phases: Development phase and Production phase.

In the development phase, we run the java server and the Angular app on completely different ports. It's easier and faster to develop that way. If you look at the following diagram the Angular app is running on port **4200** with the help of a webpack dev server and the java server is running on port **8080**.

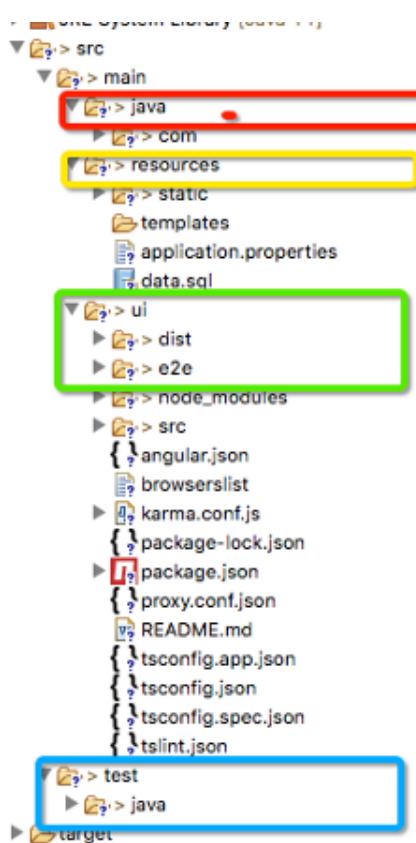

Project Structure

Let's understand the project structure for this project. We need to have two completely different folders for java and angular. It's always best practice to have completely different folders for each one. In this way, you will have a clean architecture or any other problems regarding merging any files.

Project Structure

Project Structure

If you look at the above project structure, all the Angular app resides under the ***src/main/ui*** folder and Java code resides under the ***src/main/java*** folder. All the resources are under the folder ***/src/main/resources*** such as properties, static assets, etc

Java API

We use spring boot and a lot of other tools such as Spring Devtools, Spring Actuator, etc under the spring umbrella. Nowadays almost every application has spring boot and it is an open-source Java-based framework used to create a micro Service. It is developed by the Pivotal Team and is used to build stand-alone and production-ready **spring** applications.

We start with Spring initializr and select all the dependencies and generate the zip file.

The screenshot shows the Spring Initializr interface. In the 'Project' section, 'Maven Project' is selected. Under 'Language', 'Java' is chosen. In the 'Spring Boot' section, '2.2.6' is selected. On the right, the 'Dependencies' sidebar lists several optional tools: 'Spring Boot DevTools' (selected), 'Lombok', 'Rest Repositories HAL Browser', 'Spring HATEOAS', and 'Spring Web'. At the bottom, there are 'GENERATE' and 'SHARE...' buttons, and a download link for 'users.zip'.

Once you import the zip file in the eclipse or any other IDE as a Maven project you can see all the dependencies in the **pom.xml**. Below is the dependencies section of pom.xml.

```
1 <dependencies>
2 <dependency>
3     <groupId>org.springframework.boot</groupId>
4     <artifactId>spring-boot-starter-actuator</artifactId>
5 </dependency>
6 <dependency>
7     <groupId>org.springframework.boot</groupId>
8     <artifactId>spring-boot-starter-data-jpa</artifactId>
9 </dependency>
10 <dependency>
11     <groupId>com.h2database</groupId>
12     <artifactId>h2</artifactId>
13     <scope>runtime</scope>
14     <version>1.4.199</version>
15 </dependency>
16 <dependency>
17     <groupId>org.springframework.boot</groupId>
18     <artifactId>spring-boot-starter-data-rest</artifactId>
19 </dependency>
20 <dependency>
21     <groupId>org.springframework.boot</groupId>
22     <artifactId>spring-boot-starter-hateoas</artifactId>
23 </dependency>
24 <dependency>
25     <groupId>org.springframework.boot</groupId>
26     <artifactId>spring-boot-starter-web</artifactId>
27 </dependency>
28 <dependency>
29     <groupId>org.springframework.data</groupId>
30     <artifactId>spring-data-rest-hal-browser</artifactId>
31 </dependency>
32 <!-- QueryDSL -->
33 <dependency>
34     <groupId>com.querydsl</groupId>
35     <artifactId>querydsl-apt</artifactId>
36 </dependency>
37 <dependency>
38     <groupId>com.querydsl</groupId>
39     <artifactId>querydsl-jpa</artifactId>
40 </dependency>
41 <dependency>
42     <groupId>com.h2database</groupId>
43     <artifactId>h2</artifactId>
```

```
48 <dependency>
49     <groupId>org.springframework.boot</groupId>
50     <artifactId>spring-boot-devtools</artifactId>
51     <scope>runtime</scope>
52     <optional>true</optional>
53 </dependency>
54 <dependency>
55     <groupId>org.projectlombok</groupId>
56     <artifactId>lombok</artifactId>
57     <optional>true</optional>
58 </dependency>
59 <dependency>
60     <groupId>org.springframework.boot</groupId>
61     <artifactId>spring-boot-starter-test</artifactId>
62     <scope>test</scope>
63     <exclusions>
64         <exclusion>
65             <groupId>org.junit.vintage</groupId>
66             <artifactId>junit-vintage-engine</artifactId>
67         </exclusion>
68     </exclusions>
69 </dependency>
70 </dependencies>

dependencies portion of pom.xml

Here are the spring boot file and the controller with two routes one with GET request and another is POST request.

```
1 package com.bbtutorials.users;
2
3 import org.springframework.boot.SpringApplication;
4 import org.springframework.boot.autoconfigure.SpringBootApplication;
5
6 @SpringBootApplication
7 public class UsersApplication {
8
9     public static void main(String[] args) {
10         SpringApplication.run(UsersApplication.class, args);
11     }
12
13 }
```

UsersApplication.java hosted with ❤ by GitHub

[view raw](#)

```
1 package com.bbtutorials.users.controller;
2
3 import java.util.List;
4
5 import org.springframework.beans.factory.annotation.Autowired;
6 import org.springframework.http.ResponseEntity;
7 import org.springframework.web.bind.annotation.GetMapping;
8 import org.springframework.web.bind.annotation.PostMapping;
9 import org.springframework.web.bind.annotation.RequestBody;
10 import org.springframework.web.bind.annotation.RequestMapping;
11 import org.springframework.web.bind.annotation.RestController;
12
13 import com.bbtutorials.users.entity.Users;
14 import com.bbtutorials.users.links.UserLinks;
15 import com.bbtutorials.users.service.UserService;
16
17 import lombok.extern.slf4j.Slf4j;
18
19 @Slf4j
20 @RestController
21 @RequestMapping("/api/")
22 public class UsersController {
23
24     @Autowired
25     UserService userService;
26
27     @GetMapping(path = UserLinks.LIST_USERS)
28     public ResponseEntity<?> listUsers() {
29         log.info("UsersController: list users");
30     }
31 }
```

```

34     @PostMapping(path = UserLinks.ADD_USER)
35     public ResponseEntity<?> saveUser(@RequestBody Users user) {
36         log.info("UsersController: list users");
37         Users resource = usersService.saveUser(user);
38         return ResponseEntity.ok(resource);
39     }
40 }
```

UsersController.java hosted with ❤ by [GitHub](#)

controller and the main file

Configure H2 Database

This H2 Database is for development only. When you build this project for production you can replace it with any database of your choice. You can run this database standalone without your application. We will see how we can configure with spring boot.

First, we need to add some properties to application.properties file under **/src/main/resources**

```

1  spring.datasource.url=jdbc:h2:mem:testdb
2  spring.datasource.driverClassName=org.h2.Driver
3  spring.datasource.username=sa
4  spring.datasource.password=password
5  spring.jpa.database-platform=org.hibernate.dialect.H2Dialect
6  spring.h2.console.enabled=true
```

application.properties hosted with ❤ by [GitHub](#)

[view raw](#)

application.properties

Second, add the below SQL file under the same location.

```

1  DROP TABLE IF EXISTS users;
2
3  CREATE TABLE users (
4      id INT PRIMARY KEY,
5      FIRST_NAME VARCHAR(250) NOT NULL,
6      LAST_NAME VARCHAR(250) NOT NULL,
7      EMAIL VARCHAR(250) NOT NULL
8  );
9
10 INSERT INTO users (ID, FIRST_NAME, LAST_NAME, EMAIL) VALUES
11     (1, 'first', 'last 1', 'abc1@gmail.com'),
12     (2, 'first', 'last 2', 'abc2@gmail.com'),
13     (3, 'first', 'last 3', 'abc3@gmail.com');

```

[data.sql](#) hosted with ❤ by GitHub[view raw](#)[data.sql](#)

Third, start the application and spring boot creates this table on startup. Once the application is started you can go to this URL <http://localhost:8080/api/h2-console> and access the database on the web browser. Make sure you have the same JDBC URL, username and password as in the properties file.

The screenshot shows the H2 in-memory database console interface. The URL in the address bar is <http://localhost:8080/h2-console/login.do?jsessionid=14e9949d592055fb07288e3dbd091a3e>. The left sidebar shows the database structure with 'USERS' selected. The main area contains a SQL statement 'SELECT * FROM USERS;' and its results:

ID	FIRST_NAME	LAST_NAME	EMAIL
1	first	last 1	abc1@gmail.com
2	first	last 2	abc2@gmail.com
3	first	last 3	abc3@gmail.com
4	sdfsdf	sdfsdfsdf	sdfsdfsfsdf
5	sdfsdfsdf	sdfsdf	sdfsdfsdfsdf
6	sdfsdfsdf	sdfsdfsdf	sdfsdfsdfsdf

(6 rows, 8 ms)

h2 in-memory database

Let's add the repository files, service files, and entity classes as below and start the spring boot app.

```
1 package com.bbtutorials.users.entity;
2
3 import javax.persistence.Column;
4 import javax.persistence.Entity;
5 import javax.persistence.Id;
6 import javax.validation.constraints.NotNull;
7
8
9 import lombok.Data;
10
11 @Entity
12 @Data
13 public class Users {
14
15     @Id
16     @Column
17     private long id;
18
19     @Column
20     @NotNull(message="{NotNull.User.firstName}")
21     private String firstName;
22
23     @Column
24     @NotNull(message="{NotNull.User.lastName}")
25     private String lastName;
26
27     @Column
28     @NotNull(message="{NotNull.User.email}")
29     private String email;
30
31 }
```

Users.java hosted with ❤ by GitHub

[view raw](#)

```
1 package com.bbtutorials.users.repository;
2
3 import org.springframework.data.jpa.repository.JpaRepository;
4 import org.springframework.data.jpa.repository.JpaSpecificationExecutor;
5 import org.springframework.data.querydsl.QuerydslPredicateExecutor;
6 import org.springframework.data.rest.core.annotation.RepositoryRestResource;
7
8 import com.bbtutorials.users.entity.Users;
9
10 @RepositoryRestResource()
11 public interface UsersRepository extends JpaRepository<Users, Integer>, JpaSpecification
```

```
3 import java.util.List;
4
5 import org.springframework.stereotype.Component;
6
7 import com.bbtutorials.users.entity.Users;
8 import com.bbtutorials.users.repository.UsersRepository;
9
10 @Component
11 public class UsersService {
12
13     private UsersRepository usersRepository;
14
15     public UsersService(UsersRepository usersRepository) {
16         this.usersRepository = usersRepository;
17     }
18
19     public List<Users> getUsers() {
20         return usersRepository.findAll();
21     }
22
23     public Users saveUser(Users users) {
24         return usersRepository.save(users);
25     }
26
27 }
```

UsersService.java hosted with ❤️ by GitHub

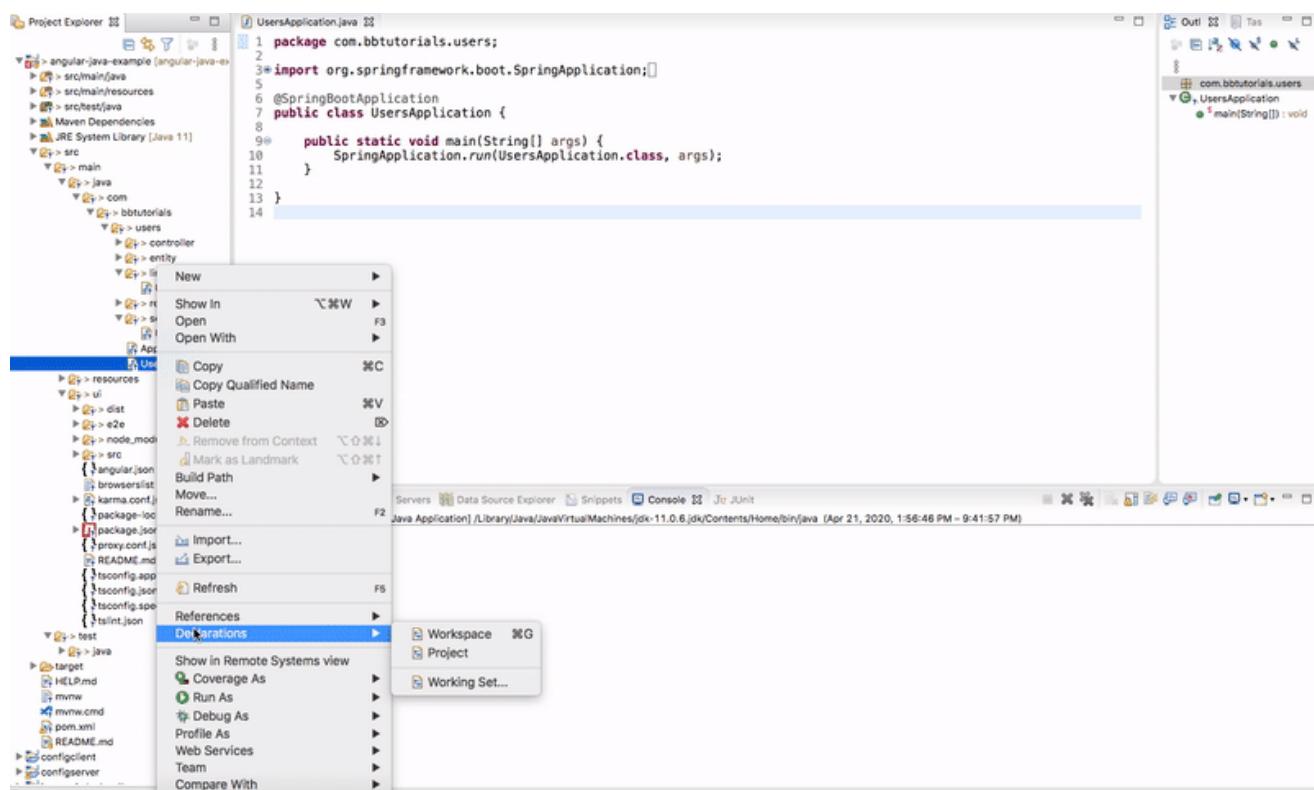

[view raw](#)

repository, service, and entity files

You can start the application in two ways: you can right-click on the UsersApplication and run it as a java application or do the following steps.

```
// mvn install
mvn clean install

// run the app
java -jar target/<repo>.war
```

starting the spring boot application

Finally, you can list all the users with this endpoint <http://localhost:8080/api/users>.

```

[
  {
    "id": 1,
    "firstName": "first",
    "lastName": "last 1",
    "email": "abc1@gmail.com"
  },
  {
    "id": 2,
    "firstName": "first",
    "lastName": "last 2",
    "email": "abc2@gmail.com"
  },
  {
    "id": 3,
    "firstName": "first",
    "lastName": "last 3",
    "email": "abc3@gmail.com"
  },
  {
    "id": 4,
    "firstName": "asdasd",
    "lastName": "asdasd",
    "email": "asdadadad"
  }
]

```

Java code running on port 8080

Angular App

Now the java code is running on port **8080**. Now it's time to look at the Angular app. The entire Angular app is under the folder **src/main/ui**. You can create with this command `ng new ui`. I am not going to put all the files here you can look at the entire files in the above Github link or [here](#).

Let's see some important files here. Here is the service file which calls Java API.

```
1 import { Injectable } from '@angular/core';
2 import { HttpClient } from '@angular/common/http';
3
4 @Injectable({
5   providedIn: 'root'
6 })
7 export class AppService {
8
9   constructor(private http: HttpClient) { }
10
11   rootURL = '/api';
12
13   getUsers() {
14     return this.http.get(this.rootURL + '/users');
15   }
16
17   addUser(user: any, id: number) {
18     user.id = id;
19     return this.http.post(this.rootURL + '/user', user);
20   }
21
22 }
```

app.service.ts hosted with ❤ by GitHub

[view raw](#)

app.service.ts

Here is the app component which subscribes to these calls and gets the data from the API.

```
1 import { Component, OnDestroy } from '@angular/core';
2 import { FormGroup, FormControl, Validators } from '@angular/forms';
3 import { AppService } from './app.service';
4 import { takeUntil } from 'rxjs/operators';
5 import { Subject } from 'rxjs';
6
7 @Component({
8   selector: 'app-root',
9   templateUrl: './app.component.html',
10  styleUrls: ['./app.component.css']
11 })
12 export class AppComponent implements OnDestroy {
13
14   constructor(private appService: AppService) {}
15
16   title = 'angular-nodejs-example';
17
18   userForm = new FormGroup({
19     firstName: new FormControl('', Validators.nullValidator && Validators.required),
20     lastName: new FormControl('', Validators.nullValidator && Validators.required),
21     email: new FormControl('', Validators.nullValidator && Validators.required)
22 });
23
24   users: any[] = [];
25   userCount = 0;
26
27   destroy$: Subject<boolean> = new Subject<boolean>();
28
29   onSubmit() {
30     this.appService.addUser(this.userForm.value, this.userCount + 1).pipe(takeUntil(this
31       console.log('message::::', data);
32       this.userCount = this.userCount + 1;
33       console.log(this.userCount);
34       this.userForm.reset());
35     );
36   }
37
38   getAllUsers() {
39     this.appService.getUsers().pipe(takeUntil(this.destroy$)).subscribe((users: any[]) =
40       this.userCount = users.length;
41       this.users = users;
42     );
43   }
44
```

app.component.ts

- How To Build Angular With Java Backend For Production Interaction between Angular and Java API

Summary In development phase, the Angular app is running on port **4200** with the help of a webpack dev server and Java API running on port **8080**. We can proxy all the API calls to Java API and ship for production.

The One way is to build Angular with Java. There should be some integration between these two. We can proxy all the API calls to Java API. Angular provides an inbuilt proxying method. First, we need to define the following proxy configuration.

- In the development phase, we can run Angular and Java on separate ports.

proxy.conf.json under **src/main/ui** folder.

- The interaction between these two happens with proxying all the calls to API.

```

1  {
2    "/api": {
3      "target": "http://localhost:8080",
4      "secure": false
5    }
6  }
```

proxy.conf.json hosted with ❤ by GitHub

[view raw](#)

proxy.conf.json

Conclusion

This is one way of building and shipping Angular apps. This is really useful when you want to do server-side rendering or you need to do some processing. In future posts, I will discuss more on building for production and deployment strategies.

```

"serve": {
  "builder": "@angular-devkit/build-angular:dev-server",
  "options": {
    "browserTarget": "angular-nodejs-example:build",
    "proxyConfig": "proxy.conf.json"
  },
  "configurations": {
    "production": {
      "browserTarget": "angular-nodejs-example:build:production"
    }
  }
},
